

Metagenomics and ecological networks

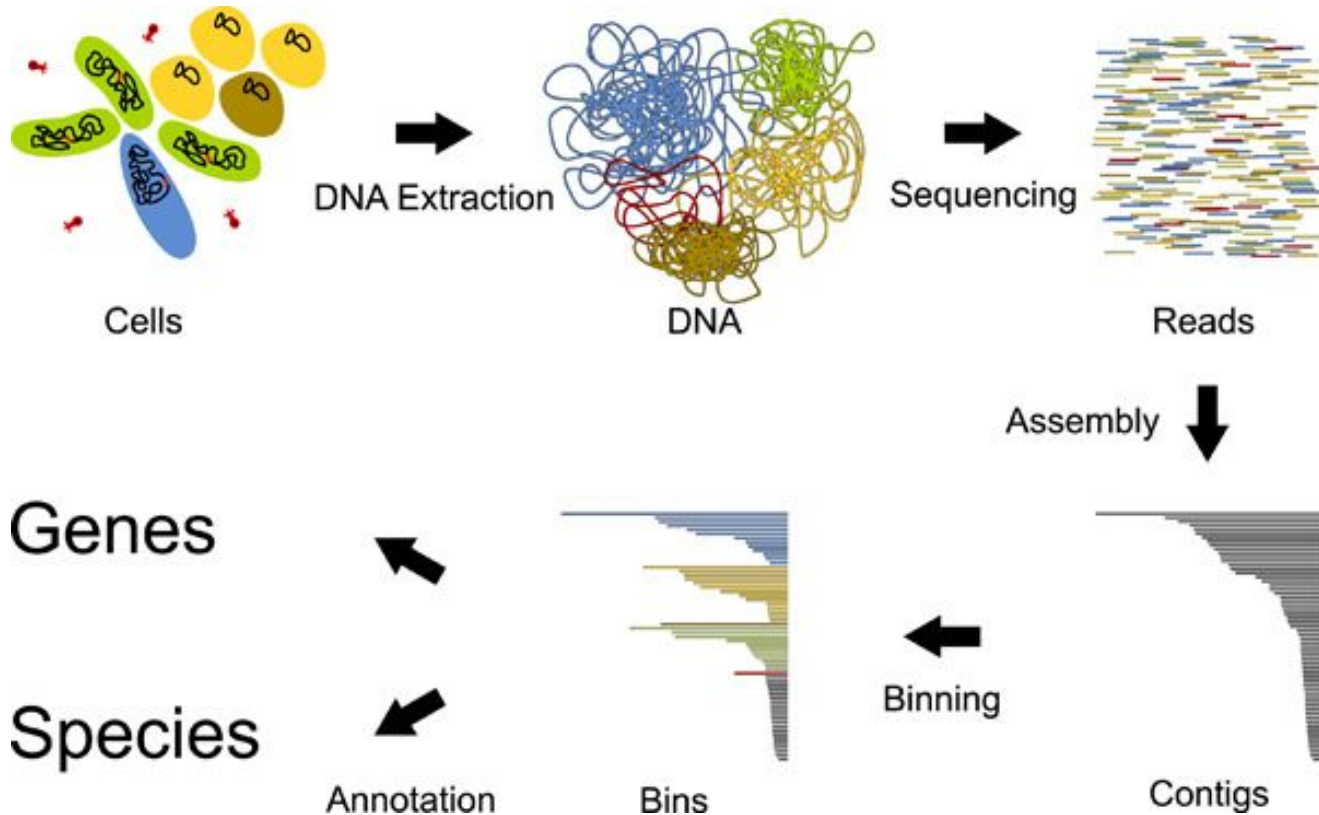

From a sample to an ecosystem

- Metagenomics
- The current state of the art
 - Assembly
 - Binning
- Extant biodiversity and the unknown
- Functional annotation
 - Structures and AI
- Finding networks and characterizing them.
- Taking an evolutionary angle relationships?

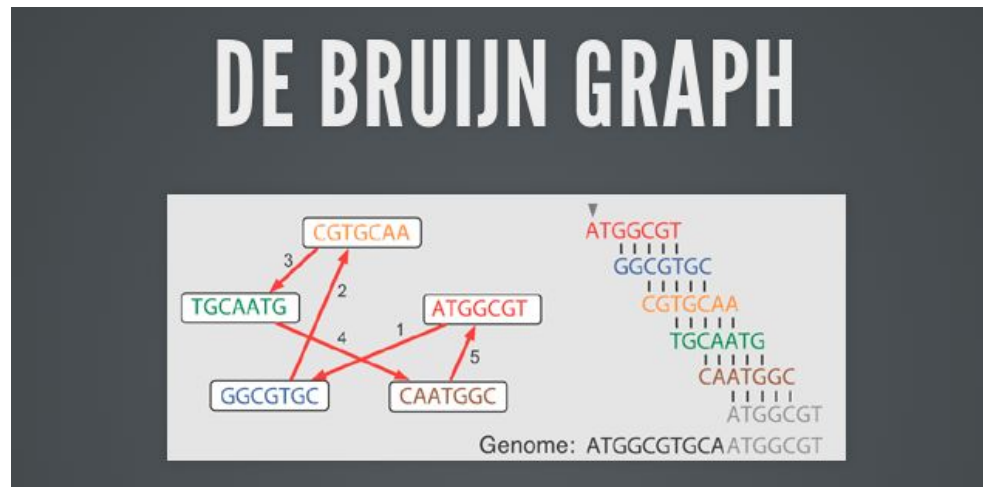

How do we even get this
data?

In a nutshell

Metagenomic Assembly

- Most approaches will use a De Bruijn graph.
 - Link all reads by the presence of shared KMERs
 - The reads are nodes on a graph.
 - The final sequence is dictated by the series of nodes the graph passes through.
- Metagenome-assembled genomes (MAGs)

Find X-structure in de Bruijn graph

Split X-structure (extend contigs)

Binning

- meta-assemble a sample of short reads into contigs
 - Then cluster contigs based on some criteria.
 - In theory each bin corresponds to a genome.
- Two criteria: KMERs and Abundance.
- Time complexity remains an issue

Binning : Grouping nucleotide sequences belonging to individual/similar organism/s

Co-abundance binning

- Across different samples
- The abundance of organisms can help group reads
- Binning the reads and then assembling increases accuracy
- Still requires substantial coverage

Kmer spectra Binning

- Words of length k in the DNA
- These are optimised by each organism for its niche
- Can be used to group reads
- Here $k=6$, 4096 possible words of length 6

Candidatus Thorarchaeota archaeon isolate B59_G1 B59_Guay1_scaffold_00001, whole genome

Natrinema altunense strain AJ2 N_altunense_AJ2_contig_1, whole genome

Metaproteomics: PLASS

- What if we don't even care about genomes?
- We lose synteny, intragenic regions etc
- We gain sensitivity!
- Bag of proteins

What's out there?

Filtering is already informative

A

Extant diversity: Viruses

- In this Tara oceans they quantify the diversity using entropic measures.

○

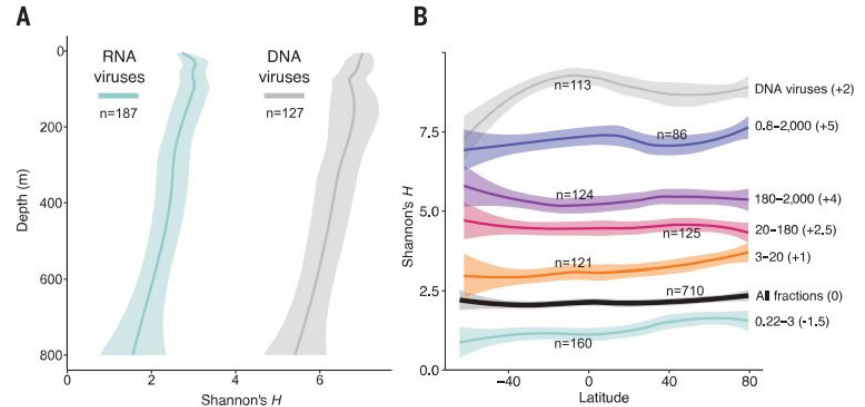

$$H = - \sum p(x) \log p(x)$$

- It varies along the sampling depth and latitude.
- We don't know what most of these viruses infect or what their viral cycle is like.
- Another study: (<6% of reads matched known viruses)

MARINE VIROME

Diversity and ecological footprint of Global Ocean RNA viruses

Open Problem: Eukaryotes!

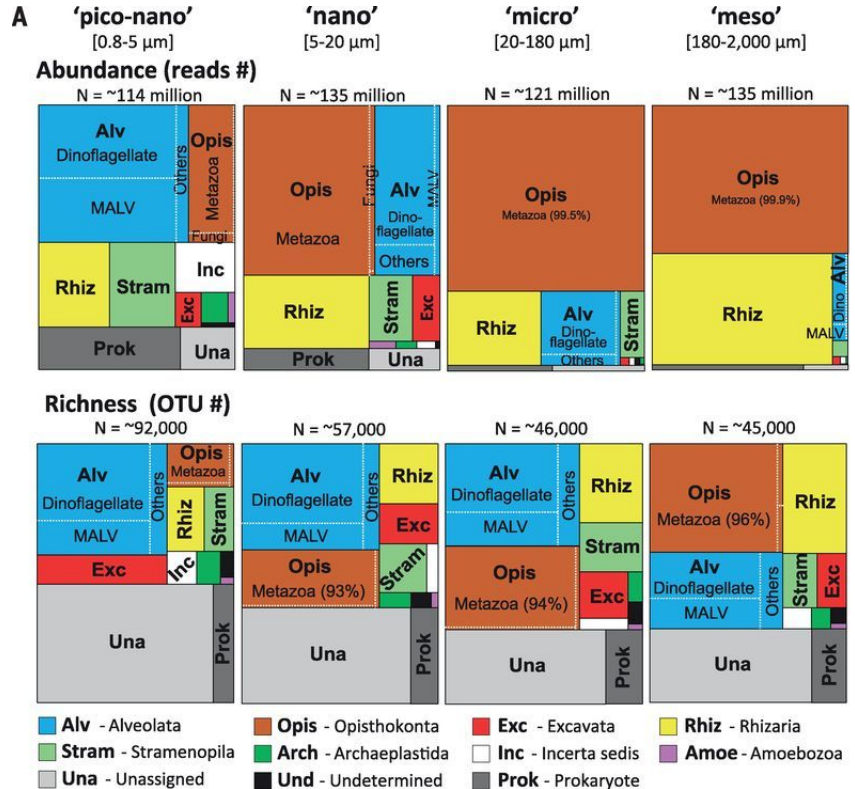

- Metagenomics assemblies are still out of reach for eukaryotes.
- Low coverage
 - We can't even attribute their rDNA!
- Many early branching species.
 - Could be crucial in understanding the emergence of eukarya from archaea.

Eukaryotic plankton diversity in the sunlit ocean

What's in their genomes?

Functional annotation

- Map to something you know...
- KEGG
- UniProt
- eggNOG (and OMA we hope soon)
- Pfam
- Transfer knowledge based on homology... to model organisms

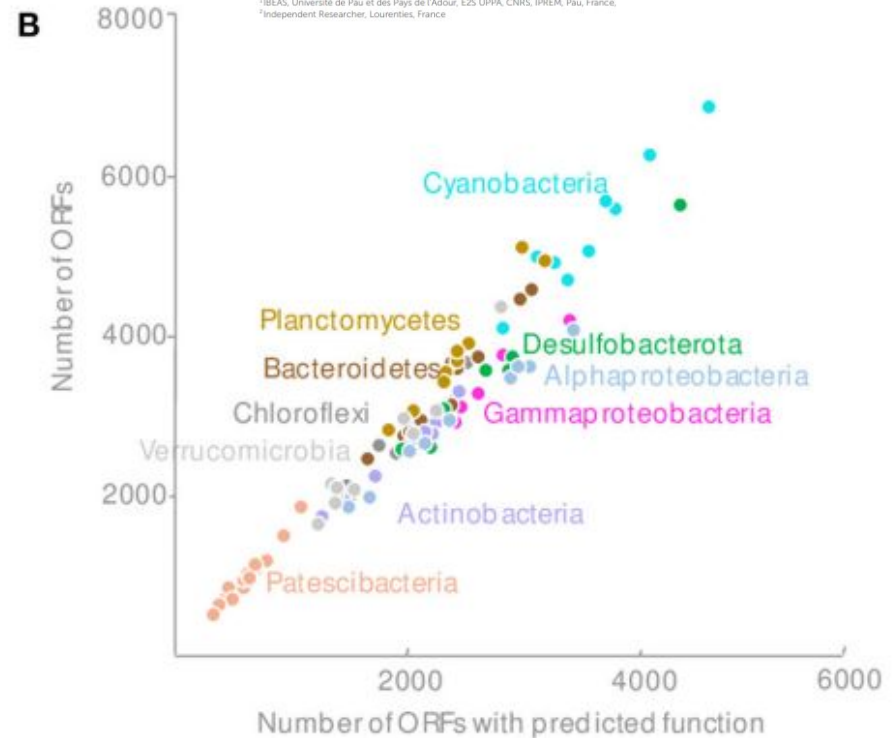

Metagenomic dark matter

- 25% or more in some cases have No Detectable Homology to anything we know.
- In the mobile fraction / pangenome this often reaches above 50%.
- In the other cases where we can map our knowledge is limited.
- How do we proceed?

Into the darkness of the microbial dark matter *in situ* activities through expression profiles of *Patescibacteria* populations

ESM: evolutionary scale model

- Form is tied to function
- We can use structural information now
- ESM folded the Mgnify database
- We now have 600 M structures attributed to MAGs

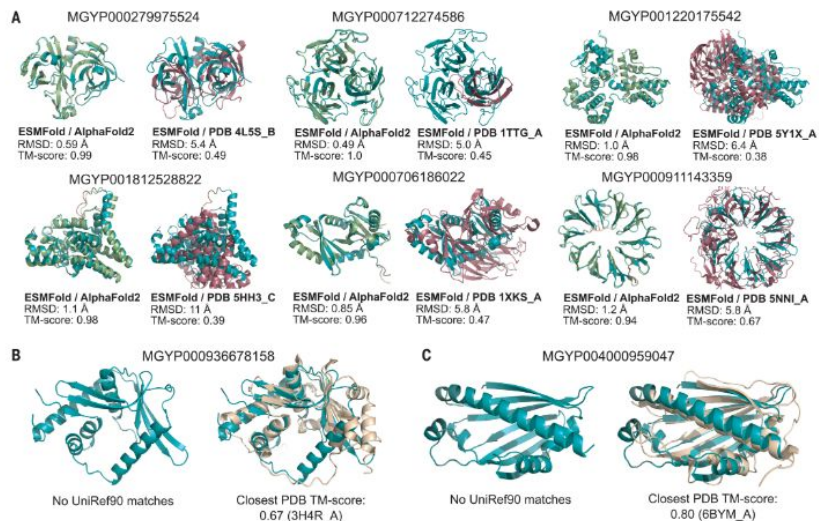

Fig. 4. Example ESMFold structure predictions of metagenomic sequences.

Greater than the sum of its parts: The ecological net.

- Organisms are metabolically complementary
- Predator prey / Symbiotic / Parasitic etc
- With each mag we build a genome scale model GSM
- Can we find the metabolic flux through each organism?
- This is more of an opinion piece...

From bag-of-genes to bag-of-genomes:
metabolic modelling of communities in the
era of metagenome-assembled genomes

[Clémence Frioux](#)^{a b} , [Dipali Singh](#)^c , [Tamas Korcsmaros](#)^{b d} , [Falk Hildebrand](#)^{b d}  

Type of modeling

Graph-based

Network expansion

Steady-state

$$S = \begin{pmatrix} +1 & \dots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \dots & -1 \end{pmatrix}$$

$$S \cdot v = 0$$

Dynamic models

$$\frac{dX_i}{dt} = \dots$$

Lumped
'bag-of-genes'

Compartmentalized
'bag-of-genomes'

Applications

- Inference of knowledge – prediction of response
- Selection of communities – keystone species
- Synthetic design – alteration of communities

Level of modeling

Top-down

Bottom-up

Metagenomics

Approach

Small-scale experiments

An example: Viral communities

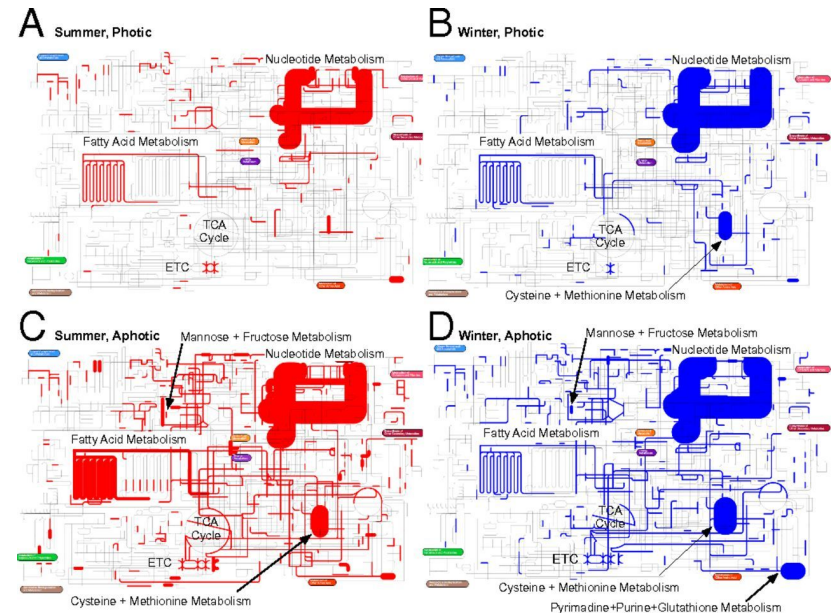

- (<6% of reads matched known viruses)
- These analyses resulted in (i) a unified comparative network of viromes based on sequence composition (Fig. 1) and (ii) a statistical measure of the effect of covariates (i.e., season, proximity to shore, and depth) on the network structure
- Looking at Kegg pathways
- Viral encoded host genes
- Summer/winter
- Shallow/deep
- What pathways are present in the population in different conditions

Modeling ecological drivers in marine viral communities using comparative metagenomics and network analyses

An evolutionary angle: When things emerged

Appears unexplored so far.

When in the species phylogeny did trophic relationships emerge?

How has gene content changed as a consequence?

Are pangenomic entities evolving as a cluster of genes separately?
